\textbf{ABSTRACT} Many \textit{Staphylococcus} and \textit{Pseudomonas} species, such as \textit{Staphylococcus aureus} and \textit{Pseudomonas aeruginosa}, are opportunistic human pathogens. However, \textit{Pseudomonas} species are also known to produce bioactive compounds. Here, we report on the genome sequences of a \textit{Pseudomonas} isolate and a \textit{Staphylococcus} species of unknown origin that it inhibits.

Many non-\textit{aureus} or non-\textit{aeruginosa} \textit{Staphylococcus} and \textit{Pseudomonas} species are known emerging pathogens (1–6). However, \textit{Pseudomonas} strains are also known to produce toxic compounds such as cyclic lipopeptides (7, 8).

A bacterial colony (CVAP#3) was isolated from a soil sample (sampled at 42°19'04.01"N, 72°38'25.60"W, at an altitude of 41.76 m, on 21 November 2014) that had been suspended in 1× phosphate-buffered saline (PBS), plated onto 10% tryptic soy agar (TSA), and incubated for 48 h at 25°C. CVAP#3 inhibited a lawn of \textit{Staphylococcus} (CWZ226) on TSA at 25°C overnight. CWZ226 is of unknown origin and is maintained in a culture collection at Smith College.

In order (i) to determine the phylogenetic position of strains CVAP#3 and CWZ226 and (ii) to identify loci for bioactive compounds against \textit{Staphylococcus}, the genomes of both strains were sequenced. To isolate DNA, the Promega Wizard genomic DNA kit was employed (catalog number A1120). The Nextera DNA Flex library preparation kit (catalog number 20018704) was used for library construction. Sequencing was performed at Smith College using the MiSeq reagent kit (cartridge) v3 for 150 cycles (catalog number MS-102-3001) or 600 cycles (catalog number MS-102-3003); this resulted in 5,050,320 and 956,980 raw reads for the paired-end reads of 75-bp and 300-bp sequences, respectively, for the CVAP#3 genome. Similarly, two sequencing runs for the \textit{Staphylococcus} genome resulted in 2,386,984 and 2,600,230 paired-end reads of 300 bp.

Both sets of paired-end reads were assembled in SPAdes v3.11.1 (9) in careful mode with the -kmer set at 73 (CVAP#3) or default (CWZ226) and a Phred offset of 33. Contigs smaller than 700 bp were removed. Metagenome binning in PATRIC v3.6.9 (10) resulted in 45 contigs and 31 contigs in one bin with 33.1× and 506× coverage for CVAP#3 and CWZ226, respectively. Comprehensive genome analysis and annotation of the CVAP#3 genome in PATRIC resulted in a total genome length of 6,255,897 bp, an \textit{N}_{50} value of 301,990 bp, and an \textit{L}_{50} value of 7. Completeness is 99.1%, the GC content is 58.7%, and a total of 58 tRNAs, 1 rRNA, 1,395 hypothetical proteins, and 4,510 known proteins were found. The analysis of the CWZ226 genome resulted in a total length of 2,557,926 bp, an \textit{N}_{50} value of 209,069 bp, and an \textit{L}_{50} value of 5. Completeness is 99.9%, the GC content is 36.1%, and a total of 57 tRNAs, 6 rRNAs, 520 hypothetical proteins, and 1,854 known proteins were found.

The 16S sequences were used as queries in the NCBI genomic database (11). The highest level of identity was with \textit{Pseudomonas fluorescens} (99.9%) (12) and \textit{Staphylococcus simulans} (99.7%) (4) for strains CVAP#3 and CWZ226, respectively. Strict analysis of the \textit{Pseudomonas} genome with antiSMASH v6.0.0 (13) resulted in seven gene clusters putatively involved in the production of secondary metabolites. Five of these gene clusters are putatively involved in the...
production of fengycin and two different siderophores, pseudomomine and pseudopyrnonine, compounds with antimicrobial and anticancer activity. In addition, two of these gene clusters code for bacteriocins and have domains associated with alkaline phosphatase and endonuclease (DUF692 domain).

**Data availability.** This whole-genome shotgun project has been deposited in DDBJ/ENA/GenBank; the accession numbers are JAHMSC000000000 for *Pseudomonas* sp. strain CVAP#3 and JAHMSB000000000 for *Staphylococcus* strain CWZ2226. All raw sequencing files can be found in the SRA under accession number SRP323427. The strains used (CVAP#3, MC4100, and CWZ2226) can be requested by email (jvriezen@smith.edu).

**ACKNOWLEDGMENTS**

This study was supported by funding from the Office of Faculty Development and Course Development at Smith College. The funders had no role in the study design, data collection and interpretation, or the decision to submit the work for publication.

Special thanks go to Sarah Sutto-Plunz for isolating the bacterium from soil, Lori Saunders for library construction, Louie Bierwert and Riccardo Racicot for sequencing, Louie Bierwert and Robin Sleith for productive conversations and advice, and Rebecca Wattam at the Biocomplexity Institute at Virginia Tech for assistance with the use of PATRIC. Special thanks go to Christine White Ziegler for providing the infrastructure and intellectual input; without it, this work would not have been done. Thanks also go to Rachel Wright for proofreading. In addition, we thank many students in the courses BIO130 and BIO205 at Smith College.
